

### Background

- ✓ **Travel time estimation and prediction on urban streets:** significant for transportation system management, traveler information and real-time routing.
- ✓ **Travel time estimation:** directly (*i.e.* probe vehicles) OR indirectly (*i.e.* loop detector data)
- ✓ **Traffic data from various sources:** different accuracy/coverage → *inconsistent travel time estimations*
- ✓ **Data fusion:** considers quality of data provided by various sources → *increase accuracy of estimations*

### Purpose

Developing data fusion techniques for:

- ✓ Travel time estimation
- ✓ Short-term travel time prediction

Fig.1 Travel time varies according to traffic conditions on urban streets

on urban arterials using data provided by different sources (*i.e.* probe vehicles, AVI system, detectors...).

### Method

1. Trajectory approximation: fixed sensor data
2. Real but partial trajectories: probe data
3. Superimpose trajectories
4. Reconstruct trajectories: considering fundamental diagram, signal timing and shockwave analysis
5. Travel time estimation
6. Short-term travel time prediction: considering signal timing and traffic conditions

Fixed sensors:

Probe sensors:

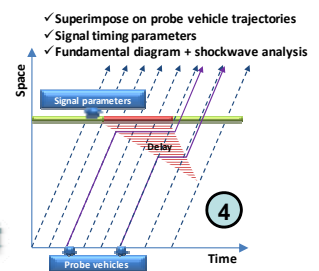

Trajectory Approximation:

Partial trajectories

Data Fusion:

Travel Time Estimation:

Traffic conditions

Travel Time Prediction

### Application

- ✓ Providing accurate and reliable travel times to road users considering current and future traffic conditions and signal control parameters
- ✓ Developing a performance measurement tool for traffic management on urban arterials
- ✓ Optimizing signal control strategies to reduce delay, improve mobility and eliminate emission

### Conclusion

- ✓ Existing fusion techniques: rely on statistical methods without considering traffic engineering principles
- ✓ Proposed methodology: implements principles of traffic engineering for fully utilization of available data and provision of accurate and robust travel time estimations and predictions.
